

Script to Populate Registration Code When Not Already There

07/19/2024 11:34 am EDT

Description of Issue:

There could be times when the registration code is not populated on the AR_Customer records.

If the code is not populated and the customer information is saved it will cause the error below.

Resolution:

If it is just one or a few you can populate the registration code by using the refresh button in the customer information screen. Then you can save the customer record.

□

If the code is missing from many customers, the script below can be executed to check and then populate the Registration code for any customer that does not have one already.

```
-- Populate registration code when not already there.

declare @CustomerId int, @code varchar(20)

declare cCustomer cursor forward_only static read_only

for

select Customer_Id from AR_Customer where isnull(Registration_Code, '') = '' order by Customer_Id

open cCustomer

fetch next from cCustomer

into @CustomerId

while @@fetch_status = 0

begin

    GetCode:

    execute dbo.Generate_Random_Code 6, @code output

    if exists (select Customer_Id from AR_Customer where Registration_Code = @code)

        goto GetCode

    update AR_Customer set Registration_Code = @code where Customer_Id = @CustomerId

    fetch next from cCustomer

    into @CustomerId

end

close cCustomer

deallocate cCustomer

go
```
